Hello Taylor,

Following up on our discussion, we are primarily focusing on preventive care. A number of our patients have an unhealthy diet that primarily includes high-sugar, high-calorie products. As a result, these patients tend to be more at risk for certain diseases, including type 2 diabetes.

What we are looking for is a tool to help our physicians identify patients at the highest risk. We would like you to start by focusing solely on demographic data (name, age, etc.). This will allow us to input and review a patient's basic information. The risk of developing diabetes increases with age, especially if poor dietary habits are not corrected.

Next, we would like you to enable physicians to add notes in the form of reports after a patient's visit. This should allow us to track potentially risky behaviors.

The last part is the most important. We need to generate a report indicating the probability of a patient developing diabetes. We will provide the factors that can lead to the disease later on.

I am looking forward to seeing what you can develop for us.

Best regards,
Ramesh
